# 1. Introduction

The IDT ZMOD4410 Gas Sensor Module is designed for monitoring indoor air quality (IAQ) by detecting total volatile organic compounds (TVOC). Both TVOC and the more familiar gas carbon dioxide (CO<sub>2</sub>) are among the factors in IAQ, and both are emitted by humans. Since CO<sub>2</sub> is better understood by the general public than TVOC, IDT has developed methods of estimating CO<sub>2</sub>. The correlation between TVOC and CO<sub>2</sub> concentration has been investigated for indoor environments and implemented in IDT's algorithm libraries.

For an additional overview of the methodology used for the ZMOD4410, refer to the *ZMOD4410 Datasheet* and the *White Paper – TVOC and Indoor Air Quality*.

# 2. Rationale for Monitoring Carbon Dioxide

Carbon dioxide (CO<sub>2</sub>) in the ambient air has negative influences on human productivity and causes effects such as dizziness, weakness, dyspnea, and even unconsciousness up to death. Depending on the country and its legislation, there are variations in the maximum level of CO<sub>2</sub> that can be considered to be "Good Air." Table 1 gives an overview of CO<sub>2</sub> levels that should not be exceeded for long-term exposure ("Safe Level") or an 8-hour day ("Critical Level"). Carbon dioxide is dangerous because it has no smell and no visible color; therefore it is not detectable by humans without additional instrumentation.

**Table 1. Warning Levels for Carbon Dioxide**

Name of Standard	Safe Level [ppm]	Critical Level [ppm]	Year of Publication
Pettenkofer Number, Germany <sup>1</sup>	< 1000		1858
German Federal Environmental Agency (UBA), Germany <sup>1</sup>	< 1000	> 2000	2008
American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE), USA <sup>2</sup>	< 1000	> 5000	2016
Indian Society of Heating, Refrigerating, and Air Conditioning Engineers (ISHRA), India <sup>3</sup>	< 1200	> 1200	2015

In general, CO<sub>2</sub> sources can be divided into natural and artificial sources. Examples of natural sources include humans, animals, and plants, which generate CO<sub>2</sub> by respiration. Examples of artificial sources include fire, carbonated drinks, and volcanos. A special property of natural sources, such as humans and animals, is that they produce VOCs (volatile organic compounds) proportional to their exhaled CO<sub>2</sub>. This fact can be used to derive an estimate for CO<sub>2</sub> concentration from the concentration of TVOCs (total volatile organic compounds).

Knowing the actual indoor CO<sub>2</sub> concentration is useful for many applications. For instance, room ventilation systems can be automatically turned on for high CO<sub>2</sub> concentrations.

Conventionally, CO<sub>2</sub> is measured using CO<sub>2</sub> sensitive sensors or very sophisticated instruments, such as spectroscopic infrared sensors (NDIR). However, these instruments are expensive and rather large compared to other sensors. Chemical sensors, such as solid sodium-superionic conductor (NASICON) electrolyte sensors, on the other hand, may be used but suffer from high drift and a short lifetime.

Alternatively, it is well known that TVOC sensors, such as IDT's ZMOD4410 metal oxide (MO<sub>x</sub>) gas sensor module, provide a very reliable method for accurately determining TVOC concentrations. Based on the assumption that the TVOC produced by humans is proportional to their exhaled CO<sub>2</sub>, these sensors can be used to estimate a CO<sub>2</sub> concentration indoors. In order to distinguish between an estimated CO<sub>2</sub> concentration and a true CO<sub>2</sub> measurement, the term eCO<sub>2</sub> (estimated CO<sub>2</sub> concentration) is used.

### 3. Description of the Working Principle

#### 3.1 Existing Approaches

MO<sub>x</sub> sensors can be used to measure the TVOC concentration and calculate an estimate of the human-generated CO<sub>2</sub> concentration (eCO<sub>2</sub>) based on the measured TVOC concentration. Most existing sensor products consider a simple constant proportionality between TVOC and emitted CO<sub>2</sub> concentration as shown in Equation 1:

$$eCO_2 = a + b * TVOC \quad \text{Equation 1}$$

where  $b$  is the constant ratio between the humanly generated CO<sub>2</sub> and TVOC and  $a$  is a constant offset.

Sometimes linear filtering is applied to reduce noise or to remove spikes and notches.

#### 3.2 IDT Smart Algorithm

Although metal oxide sensors offer state-of-the-art technology, applying a linear correlation between TVOC and CO<sub>2</sub> as in Equation 1 is insufficient for most scenarios. In a more realistic scenario, artificial sources of both TVOC and CO<sub>2</sub> must be taken into account. These include artificial CO<sub>2</sub> sources and also TVOC sources such as deodorants, air freshener, white board cleaner, cooking odors, etc. Unlike artificial CO<sub>2</sub> sources, artificial TVOC sources only increase the TVOC but do not contribute to the CO<sub>2</sub> concentration. Thus, the assumption of Equation 1 used in existing eCO<sub>2</sub> technology is not complete and will lead to large errors in the estimated CO<sub>2</sub> concentration. Even algorithmic post-processing tools such as linear low-pass filtering are not suitable to suppress these non-human TVOC sources.

The accuracy of the estimated CO<sub>2</sub> concentration can be much improved by introducing the following boundary conditions. For the lower limit, the CO<sub>2</sub> concentration in the earth's atmosphere is about 400ppm, which means that an indoor concentration cannot be lower than this value. Hence, this can be seen as a lower concentration boundary. For the upper limit, it has been proven that concentrations above 5000ppm are extremely unlikely in home or indoor environments.

In addition, with the assumption that natural CO<sub>2</sub> sources will only lead to slow changes in the CO<sub>2</sub> concentration, rapid increases or decreases in the eCO<sub>2</sub> can be attributed to artificial VOC sources or sudden regeneration of the indoor air; for example, by ventilation. Thus, IDT's smart eCO<sub>2</sub> algorithm does not only apply a linear correlation between TVOC and eCO<sub>2</sub> but also considers the time dependence of the TVOC concentration.

The differentiation between natural and artificial CO<sub>2</sub> sources is illustrated by the two measurement series in Figure 1 and Figure 2. Both data were recorded using ZMOD4410 gas sensor modules.

Figure 1 shows a measurement series taken in a kitchen over a period of 1 hour. At the beginning of the data acquisition, people enter and leave the kitchen and the TVOC (ordinate y-axis in mg/m<sup>3</sup>) level rises, as well as the eCO<sub>2</sub> (ordinate y-axis in ppm). However, during cooking, only the TVOC level rises from kitchen odors while the eCO<sub>2</sub> level remains constant.

**Figure 1. Example of a Typical Measurement in a Kitchen**

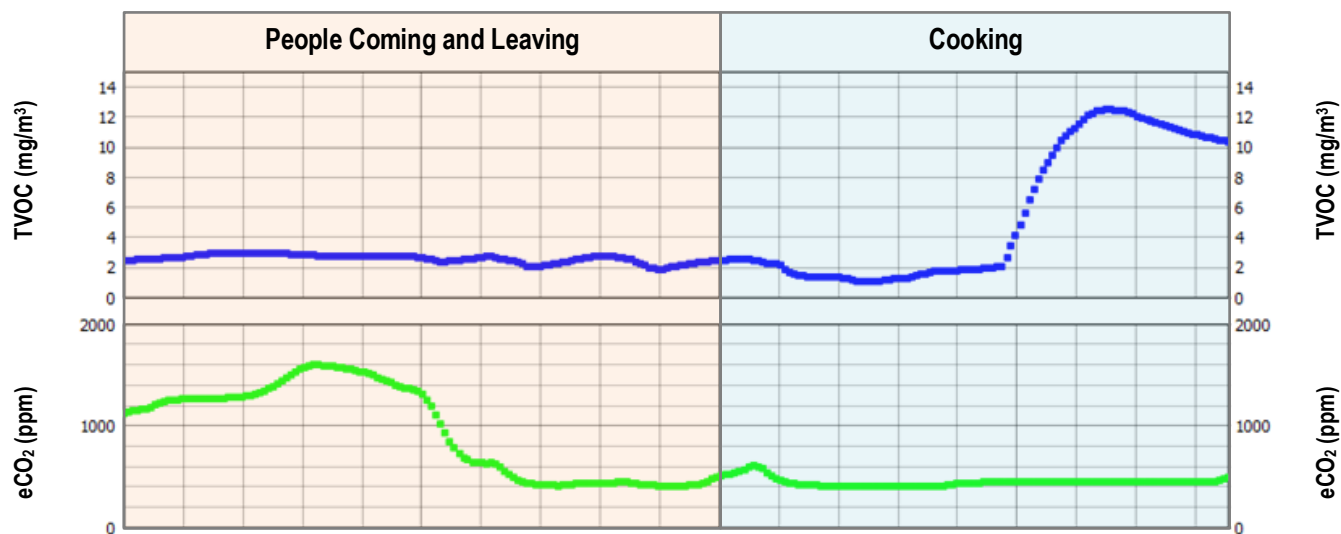

Figure 2 shows data measured in a bedroom over a period of 18 hours. The presence of people leads to a slow increase of the TVOC and eCO<sub>2</sub>, while opening the window in the evening and morning leads to rapid decreases of both gas concentrations.

**Figure 2. Example of a Typical Measurement in a Bedroom**

## 4. Sensor Results

There are various technologies and sensors on the market claiming to have a reliable carbon dioxide measurement. The most commonly used tools for extremely accurate measurements are nondispersive infrared sensor (NDIR) instruments, which are too expensive for a mass market use. To ensure the best possible comparison to a high-end CO<sub>2</sub> reference instrument, a validation study was completed using different NDIR instruments first to validate the CO<sub>2</sub> measurement consistency.

IDT's approach to measure the TVOC and estimate the CO<sub>2</sub> concentration is superior in the market for metal-oxide sensors. It is reliable with a high conformity from sensor to sensor. Compared to competitors' products offering a similar approach by estimating CO<sub>2</sub> via the TVOC measurement, the IDT patent pending algorithm has an advantage.

### 4.1 Validation of Reference Technology

As there are many CO<sub>2</sub> measurement instruments on the market, a careful choice had to be made to select a suitable reference instrument for IDT's measurements. In a first step, a comparison was made between a high-end and standard NDIR instrument. Figure 3 shows the simultaneously measured CO<sub>2</sub> concentrations of both devices.

**Figure 3. Analysis of Measurement Consistency for Two NDIR Instruments for Use as Reference Instruments**

The x-axis and y-axis show the simultaneously measured CO<sub>2</sub> concentrations of the high-end and standard NDIR CO<sub>2</sub> instrument respectively. The solid green line corresponds to a direct proportionality between both CO<sub>2</sub> concentrations. As can be seen, there is an excellent agreement between both devices with an accuracy of approximately 10% (green shaded region). The relative agreement between both instruments validates the use of the high-end NDIR as the reference instrument for validation measurements.

### 4.2 Reliability of IDT Gas Sensor Modules

The correlation between TVOC and eCO<sub>2</sub> has been carefully investigated for IDT ZMOD4410 gas sensor modules over a time period of one year in an indoor office environment. During these measurements, the reference NDIR instrument was calibrated once a week, and the ZMOD4410 were operated continuously without calibration or synchronization. Figure 4 shows the results of three ZMOD4410 sensor modules, which were operated in close proximity to the high-end NDIR instrument.

In Figure 4, the estimated carbon dioxide levels (eCO<sub>2</sub>) from the ZMOD4410s are plotted against the true CO<sub>2</sub> concentration measured by the high-end NDIR CO<sub>2</sub> instrument (see section 4.1). Ideally, the estimated CO<sub>2</sub> should follow the solid green line in each graph in Figure 4 and stay within a tolerance band of 40% (green-shaded area) or  $\pm 200$ ppm (whichever is larger). Red dots are the measurement points of the ZMOD4410s. The blue bars mark the 90% confidence intervals averaged over a 100ppm-wide concentration range.

**Figure 4. Comparison of Three IDT ZMOD4410 Gas Sensor Modules**

As can be seen, IDT's ZMOD4410s TVOC to eCO<sub>2</sub> algorithm provides an excellent correlation with the validated high-end reference instruments. Also, there is a very good sensor to sensor consistency.

### 4.3 Competitive Comparison

In order to show the superiority of IDT's gas sensor modules and algorithm over competitors, IDT has investigated several competitors' CO<sub>2</sub> gas sensors in parallel with IDT's ZMOD4410 sensor modules.

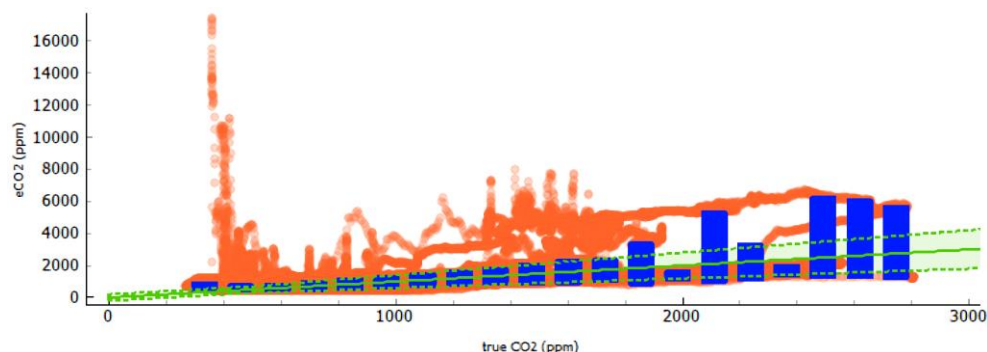

Figure 5 shows the data taken with a MOx sensor from competitor #1. Although lower and upper limits of 400ppm and 8000ppm respectively have been implemented in this sensor, there is hardly any correlation between their TVOC and eCO<sub>2</sub>. Especially at lower concentrations, the competitor's algorithm fails completely because of the fundamental correlation issues discussed in section 3.1.

**Figure 5. Analysis of Competitor #1**

The investigated MOx sensor from competitor #2 already uses a smarter algorithm possibly connected to their Multi-Pixel MOx approach. The data in Figure 6 shows an extremely large range of CO<sub>2</sub> measurements with a pronounced mismatch especially at low concentrations. This competitor claims a CO<sub>2</sub> measurement accuracy of  $\pm 15\%$ , which is disproven with these measurements.

**Figure 6. Analysis of Competitor #2**
